

SABA's Suggested minimum requirements

These requirements are based on the intended target animal's weight, the type of broadhead, and the arrow's total weight, and is provided as a *required arrow speed*. These values can be used for bow- and crossbow hunting. Note that although kinetic energy features in these tables as an intermediate value the physics and experience shows that arrow momentum has a better correlation to penetration depth. KE is just more convenient to use as intermediate value.

Steps to determine the suggested arrow speed for a particular animal:

- 1) From Table 1, read the penetration index(#1 - #200).
 - 2) Use the penetration index and the arrow weight to determine the required energy for soft tissue penetration - Table 2.
 - 3) Add to this the required energy for the hard tissue (rib) penetration - Table 3
 - 4) Use the suggested required energy and arrow weight to read the suggested minimum arrow speed - Table 4.
- When using forward opening mechanical blades, it is advised to add another 10 to 15 foot-pounds to the required kinetic energy for blade deployment.

Disclaimer: Please note that as the animal's weight is an estimation, the speed is also an estimation. Achieving the suggested required speed does not guarantee a successful hunt!

Arrow weight (grain)

www.sabowhunters.co.za

The tables implement this equation, and it is provided here only for reference:

$$E_k = \frac{D_p^2 R_i}{4502.40m} + E_b ; \text{ where } D_p = 3.5W^{0.36}, R_i = (760 R_o^{0.806})^2 \text{ and } E_b = 9.6W^{0.19}$$

R_o is the *broadhead resistance* in pounds, as measured by pushing the broadhead through 1" thick beef rump steak.

W is the estimated weight of the animal in kg.

m is the arrow's weight in grains.

The result is required kinetic energy for the specific arrow.
